Abstract. In this paper, we present sequent calculus for branching-time temporal logic with until operator. This sequent calculus uses efficient loop-check technique. We prove that we can use not all but only several special sequents from the derivation tree for the loop-check. We use indexes to discover these special sequents in the sequent calculus. These restrictions let us to get efficient decision procedure based on introduced sequent calculus.

Keywords: sequent calculus, branching-time temporal logic, until operator, loop-check.

1. Introduction

Usual sequent calculi with cut rule are practically unusable in automated environment. So, sequent calculi with analytic cut, or infinitary rule, or some kind of the loop-check must be used to get a decision procedure. Unfortunately, such a sequent calculi are inefficient and need additional modifications to get more or less usable decision procedure. One of the possibilities is constructing sequent calculi with an efficient loop-check (as it is done for some modal logics in [3]), or (if it is only possible) loop-check free calculi (as it is done for KD45 logic in [1]).

There is known sequent calculus for linear temporal logic with until which is cut free and invariant free sequent calculus [2]. Another cut free and invariant free sequent calculus for branching-time temporal logic with until operator may be find in [5] (as a special fragment of the presented sequent calculus for BDI logic). Both calculi requires loop-check to get decision procedure. In the first paper, loop leads only to non-derivable sequent. In the second paper, loop leads to non-derivable sequent or to special loop-axiom. We will define restrictions for a loop-check applicable for both cases. In this paper we concentrate on the branching-time temporal logic with modal operators: ◦ (‘next’), A(φ ∪ ψ) (‘in all futures until’) and E(φ ∪ ψ) (‘in at least one future until’). Restrictions allows us to use only special sequents in a loop-check.

We define formula in a usual way. In details logic semantics is described in [5].

DEFINITION 1. We say that sequent S is an ancestor of the sequent S’ in the derivation tree, if there exist sequence of the sequents S1 = S, S2,..., Sn = S’ that for every i = 1, 2,..., (n − 1), sequent Si is a conclusion and sequent Si+1 is a premise of some rule application.
DEFINITION 2. We say, that we have a loop $S \leadsto S'$ in the sequent derivation tree if the following conditions are true:
- sequent $S$ is an ancestor of the sequent $S'$;
- $S'$ may be obtained from $S$ by rule (Weak) application: $\frac{S}{S}$ (Weak).

DEFINITION 3. We say, that sequent $S'$ is a loop-axiom if there exists sequent $S$ satisfying the following conditions:
- $S \leadsto S'$ is a loop in the derivation tree;
- between sequents $S$ and $S'$, there exists such a rule (AU − L) or (EU − L) application, that its right premise is sequent $S'$ ancestor.

We have sequent calculus for branching-time temporal logic, which uses loop-check [5]. Sequent calculus has logical rules and the following rules:

\[
\begin{align*}
\psi, \Gamma &\rightarrow \Delta, \phi, \circ \Sigma (\phi \cup \psi), \Gamma \rightarrow \Delta, \Sigma (U-L) \\
\Gamma &\rightarrow \psi, \phi, \Delta, \Gamma \rightarrow \psi, \circ \Sigma (\phi \cup \psi), \Delta, \Sigma (U-R) \quad \Sigma \in \{A, E\}
\end{align*}
\]

(\(\Theta\) is at most one formula).

DEFINITION 4. Sequent calculus for branching-time temporal logic with inference rules (\(\lor\) L), (\(\lor\) R), (\& L), (\& R), (\(\neg\) L), (\(\neg\) R), (AU − L), (EU − L), (AU − R), (EU − R), (\(\circ\)), (Weak), with a loop-axiom and with an axiom $\Gamma, \phi \rightarrow \Delta, \phi$ we call sequent calculus $PTL_1$.

2. Restrictions for the loop-check

There is known decision procedure (described in [5]) for sequent calculus $PTL_1$. Unfortunately, this procedure use direct loop-check technique to detect non-derivable sequent, or to detect loop-axiom.

In other words, we have to deal with two types of the loops. One is a loop-axiom (Definition 3) which may lead initial sequent to be derivable. For this type of the loop we use term loop-axiom. Other is a simple loop, which is not a loop-axiom, and leads initial sequent to be non derivable. For this type of the loop we use term ‘nonderivable’ loop. We use term loop to denote both types of the loop. All restrictions for loop check presented in this paper are applied for both loop types.

DEFINITION 5. Sequent $S$ is primary if $S$ has the shape $\Sigma, \circ \Gamma \rightarrow \Pi, \circ \Delta$ and formula sets $\Sigma, \Pi$ contains only propositional variables, $\Sigma \cap \Pi = \emptyset$.

DEFINITION 6. Sequent calculus with inference rules (\(\lor\) L), (\(\lor\) R), (\& L), (\& R), (\(\neg\) L), (\(\neg\) R), (AU − L), (EU − L), (AU − R), (EU − R), (\(\circ\)), (Weak), with a loop-axiom and with an axiom $\Gamma, \phi \rightarrow \Delta, \phi$ we call sequent calculus $PTL_2$.

\[
\begin{align*}
\Gamma &\rightarrow \Theta_i \\
\Sigma, \circ \Gamma &\rightarrow \Pi, \circ \Theta_1, \ldots, \circ \Theta_n (\circ \rho),
\end{align*}
\]

where $\Sigma, \Pi$ contains only propositional variables and $\Sigma \cap \Pi = \emptyset$. 
Simple speaking, rule \((\circ_p)\) may be applied only for primary sequent.

**Lemma 1.** Sequent \(S\) is derivable in sequent calculus \(PTL_1\) if and only if sequent \(S\) is derivable in sequent calculus \(PTL_2\).

Now we introduce sequent calculus \(PTL_3\) which uses loop-check only for sequents those are some premises of the rule \((\circ_p)\) application. This modification reduces the number of the checked sequents in the derivation tree.

**Definition 7.** Loop \(S \leadsto S'\) is a \(\circ\)-loop if there exist primary sequents \(S_1, S'_1\) in the derivation tree, and \(S_1\) is obtained from the sequent \(S\), and \(S'_1\) is obtained from the sequent \(S'\) by rule \((\circ_p)\) applications (i.e., \(\frac{S'}{S_1}(\circ_p), \frac{S}{S'_1}(\circ_p))\).

**Definition 8.** We say, that sequent \(S'\) is a \(\circ\)-loop-axiom if there exists sequent \(S\) satisfying the following conditions:

- \(S \leadsto S'\) is a \(\circ\)-loop in the derivation tree,
- \(S \leadsto S'\) is a loop-axiom.

**Definition 9.** Sequent calculus with inference rules \((\lor L), (\lor R), (\& L), (\& R), (\neg L), (\neg R), (AU - L), (EU - L), (AU - R), (EU - R), (\circ_p)\), with \(\circ\)-loop-axiom and with an axiom \(\Gamma, \phi \rightarrow \Delta, \phi\) we call sequent calculus \(PTL_3\).

**Lemma 2.** Sequent \(S\) is derivable in sequent calculus \(PTL_2\) if and only if sequent \(S\) is derivable in sequent calculus \(PTL_3\).

Now we prove some lemmas to introduce main restrictions to the loop-check used. First, we define subformulas and prove some features for them.

**Definition 10.** We define formulas \(F\) extended set \(\text{Ext}(F)\) as follows:

- \(\text{Ext}(A(\phi \cup \psi)) = \text{Ext}(\circ A(\phi \cup \psi)) = \{A(\phi \cup \psi), \circ A(\phi \cup \psi)\}\),
- \(\text{Ext}(E(\phi \cup \psi)) = \text{Ext}(\neg E(\phi \cup \psi)) = \text{Ext}(\circ \neg E(\phi \cup \psi)) = \text{Ext}(\neg \circ \neg E(\phi \cup \psi)) = \{E(\phi \cup \psi), \neg E(\phi \cup \psi), \circ \neg E(\phi \cup \psi), \neg \circ \neg E(\phi \cup \psi)\}\),
- otherwise \(\text{Ext}(F) = \emptyset\).

**Definition 11.** We write \(F \subseteq_{sf} G\) to define that \(F\) is subformula of \(G\).

We use extended term subformula: if \(F \in \text{Ext}(G)\), then also \(F \subseteq_{sf} G\).

It is evident, that if \(F \subseteq_{sf} G\) and \(G \subseteq_{sf} F\), then \(F, G \in \text{Ext}(F) = \text{Ext}(G)\).

**Definition 12.** Formula \(F\) is proper subformula of \(G\) (we write \(F \subset_{sf} G\)), if \(F \subseteq_{sf} G\) and formula \(G\) length is greater than formula \(F\) length.

**Definition 13.** Formula \(F\) in sequent \(S\) is ground if for every formula \(G \in S\), formula \(F\) is not a proper subformula of \(G\) (\(F \not\subset_{sf} G\)).
It is evident, that if formula \( F \) is ground in sequent \( S \) and \( F \subseteq_{sf} G \) for some formula \( G \in S \), then \( F, G \in \text{Ext}(F) = \text{Ext}(G) \).

**Lemma 3.** If \( F \subseteq_{sf} G \) and \( G \subseteq_{sf} H \) (or \( F \subseteq_{sf} G \) and \( G \subseteq_{sf} H \)), then \( F \subseteq_{sf} H \)

or formulas \( F, G, H \in \text{Ext}(F) = \text{Ext}(G) = \text{Ext}(H) \).

**Proof.** It is evident, that \( F \subseteq_{sf} H \). Therefore, \( F \subseteq_{sf} H \) (satisfies lemma) or \( H \subseteq_{sf} F \). In the second case, we get that \( F, G, H \in \text{Ext}(F) = \text{Ext}(G) = \text{Ext}(H) \), because \( H \subseteq_{sf} F \subseteq_{sf} G \subseteq_{sf} H \).

We have to notice that \( F \) has one of the shape: \( A(\phi \cup \psi), \circ A(\phi \cup \psi) \), \( E(\phi \cup \psi), \circ E(\phi \cup \psi), \neg \circ E(\phi \cup \psi) \) if \( \text{Ext}(F) \neq \emptyset \).

**Lemma 4.** If \( S \leadsto S' \) is a \( 0 \)-loop and \( T \) is any sequent inside this loop, then any ground formula \( F \) in sequent \( T \) is such, that \( \text{Ext}(F) \neq \emptyset \).

**Proof.** Since \( S \leadsto S' \) is a \( 0 \)-loop, there exists such a sequent \( S'_1 \), that \( S'_1 \) is obtained from the sequent \( S' \) by rule \( (o_p) \) application \( (\Sigma_{S'_1}(o_p)) \).

There exists ground formula \( G \in S \), that \( F \subseteq_{sf} G \), \( G \in S' \) and \( oG \in S'_1 \), because \( S \leadsto S' \) is a \( 0 \)-loop. There exists ground formula \( H \in T \), that \( oG \subseteq_{sf} H \).

We have, that \( F \subseteq_{sf} G \), \( G \subseteq_{sf} oG \), \( oG \subseteq_{sf} H \). So, according to Lemma 3, \( F \subseteq_{sf} H \) (we get a contradiction, because \( F \) is ground formula in \( T \)), or \( F, G \in \text{Ext}(F) = \text{Ext}(G) \neq \emptyset \) (satisfies lemma).

**Lemma 5.** Suppose, that \( S \leadsto S' \) is a \( 0 \)-loop in the derivation tree constructed according sequent calculus \( \text{PTL}_3 \). If \( F \) is ground formula in sequent \( S \) or in sequent \( S' \), then for every sequent \( T \) in \( 0 \)-loop \( S \leadsto S' \) there exist formula \( F' \in \text{Ext}(F) \), which is ground in \( T \).

**Proof.** Every rule premise contains only subformulas of the rule conclusion.

Case 1) Ground formula \( F \in S \). Then \( F \in S' \), because \( S \leadsto S' \) is a \( 0 \)-loop.

Suppose, that formula \( F \) is not ground on some sequent \( T \) inside the \( 0 \)-loop \( S \leadsto S' \). So, there exist ground formula \( G \in T \), that \( F \subseteq_{sf} G \).

There exist ground formula \( H \in S \), that \( G \subseteq_{sf} H \). According to Lemma 3, \( F \subseteq_{sf} H \in S \) (contradiction for \( F \) being ground in \( S \)), or \( G \in \text{Ext}(F) \) and \( G \) is ground in \( T \) (satisfies lemma). We got that if \( F \) is ground in sequent \( S \), then for any sequent \( T \) in a \( 0 \)-loop \( S \leadsto S' \) there exist formula \( F' \in \text{Ext}(F) \) which is ground in \( T \).

Case 2) Ground formula \( F \in S' \). Suppose, that formula \( F \) is not ground on some sequent \( T \) inside the \( 0 \)-loop \( S \leadsto S' \). So, there exist ground formula \( G \in T \), that \( F \subseteq_{sf} G \).

There exist ground formula \( H \in S \), that \( G \subseteq_{sf} H \). According to Lemma 3, \( F \subseteq_{sf} H \) or \( G \in \text{Ext}(F) \) (satisfies lemma). In the case \( F \subseteq_{sf} H \), we have that \( H \in S' \), because \( S \leadsto S' \) is a \( 0 \)-loop. Formula \( F \) is ground in \( S' \). Therefore, \( F \not\subseteq_{sf} H \), and we get a contradiction, because \( F \subseteq_{sf} H \).
Corollary 1. If we have derivation tree satisfying the following items:

- we have rule application with conclusion $T$ and premise $T'$,
- there exist ground formula $F$ in the sequent $T$,
- there is no ground formula $F' \in \text{Ext}(F)$ in sequent $T'$.

Then Lemma 5 says, that sequent $T$ is not inside any $\circ$-loop $S \triangleright S'$.

Proof goes straightforward from Lemma 4 and Lemma 5.

Simple speaking, if some ground formula was deleted during some rule application (in bottom-up direction), then we do not need to check any sequent below that rule application in order to catch a loop. The main problem is to identify such a situation, because every time we delete some ground formula, at least one new ground formula appears.

Rules (in calculus $PTL_3$), those may satify above conditions, is $(AU - L)$, $(AU - R)$, $(EU - L)$, $(EU - R)$, then we take left premise (nonmodal case), or rule $(\circ_p)$. So, we can add special indexes for $\circ$-loop operators to catch such a situation.

We add different upper-indexes for every different subformula $A(\phi \lor \psi)$, $E(\phi \lor \psi)$ in the initial sequent $S$. The bottom-index will be a set of indexes. The bottom-index is defined according to the following rule:

if we have that $A^i_f(\phi \lor \psi) \subset_{sf} A^j_f(\gamma \lor \kappa)$ (or $A^i_f(\phi \lor \psi) \subset_{sf} E^j_f(\gamma \lor \kappa)$, $E^i_f(\phi \lor \psi) \subset_{sf} E^j_f(\gamma \lor \kappa)$) then $j \in U$ and $V \subset U$.

It means that every ground formula $F$ in any sequent $S$ have $\circ$-loop operator with empty set as its bottom index: $A^i_f(\phi \lor \psi)$, $\circ A^i_f(\phi \lor \psi)$, $E^i_f(\phi \lor \psi)$, $\neg E^i_f(\phi \lor \psi)$, $\neg \circ E^i_f(\phi \lor \psi)$.

Indexes are some kind of histories, because they store information about applied rules. Histories are one of the possible instruments used to make efficient loop-check (some calculi with used histories may be found in [3,4]).

Definition 14. Sequent calculus with inference rules $(\lor L)$, $(\lor R)$, $(\&L)$, $(\&R)$, $(\neg L)$, $(\neg R)$, $(AU - L^s)$, $(EU - L^s)$, $(AU - R^s)$, $(EU - R^s)$, $(\circ^s_p)$, with $\circ$-loop axiom and with an axiom $\Gamma, \phi \rightarrow \Delta, \phi$ we call sequent calculus $PTL_A$.

\[
\begin{array}{c}
\psi^*, \Gamma^* \xrightarrow{\delta} \Delta^* & \phi, \circ \Sigma^*_f(\phi \lor \psi), \Gamma \rightarrow \Delta \\
\Sigma^*_f(\phi \lor \psi), \Gamma \rightarrow \Delta & \Xi(\lor L^s) \\
& \circ \Xi = \begin{cases} 
\circ A, & \text{if } \Xi = A \\
\neg \circ \neg E, & \text{if } \Xi = E 
\end{cases} \\
\psi^*, \phi^*, \Delta^*, \Gamma \rightarrow \psi, \circ \Sigma^*_f(\phi \lor \psi), \Delta & \Xi(\lor R^s) \\
\Gamma \rightarrow \Sigma^*_f(\phi \lor \psi), \Delta & \Xi \in \{A, E\} \\
& \circ \Xi = \begin{cases} 
\circ A, & \text{if } \Xi = A \\
\neg \circ \neg E, & \text{if } \Xi = E 
\end{cases} \\
\Sigma, \circ \Gamma \rightarrow \Pi, \circ \Theta_1, \ldots, \circ \Theta_n & (\circ^s_p), \Sigma, \Pi \text{ contains only propositional variables} \\
& \Sigma \cap \Pi = \emptyset.
\end{array}
\]

Left premise of the rule $(AU - L^s)$, $(EU - L^s)$, $(AU - R^s)$, $(EU - R^s)$, $(\circ^s_p)$ is sequent $S'$ and conclusion is sequent $S$. If there is some subformula $A^i_f(\phi \lor \psi)$ or $E^i_f(\phi \lor \psi)$ in sequent $S$ and there is no such subformula (with upper-index $j$) in sequent $S'$, then $\delta = +$ and bottom-index $j$ is removed from sequent $S'$. Otherwise, $\delta = \emptyset$ (and $\Gamma^* = \Gamma$, $\Delta^* = \Delta$, $\phi^* = \phi$, $\psi^* = \psi$, $\Theta^*_i = \Theta_i$).
Simple speaking, if we got a sequent marked with +, we know, that some ground formula was just deleted and loop cannot appear here. If we delete some ground formula (we also delete some index $j$), we must get some new ground formula. These new ground formulas will be formulas containing modalized subformula with emptyset as their bottom index.

**Lemma 6.** Sequent $S$ is derivable in sequent calculus $PTL_3$ if and only if sequent $S$ is derivable in sequent calculus $PTL_4$.

The proof is straightforward from Corollary 1.

**Lemma 7.** For any sequent $S$, decision procedure based on sequent calculus $PTL_4$ terminates in finite time.

We obtain an efficient decision procedure for branching-time temporal logic if we use sequent calculus $PTL_4$ with restricted loop-check (for both loop types). Because of the restrictions during loop-check we check only sequents marked by $\circ$ and only till the first sequent marked with + (in top-down direction).

3. Conclusion

In this paper, we prove that some restrictions for loop-check for branching-time temporal logic with until operator may be applied without losing derivability. We prove that any ground formula is modalized and stable in any $\circ$-loop. These restrictions let us to construct sequent calculus with efficient loop-check, because (during loop-check) only several special marked sequents must be checked.
